

1 variable, minimal luminal diameter at the actual,
2 let's say, proximal anastomosis site might be a
3 useful observation, whether it is a primary
4 endpoint or not.

5 DR. EDMUNDS: One more would be symptoms
6 from the region at risk.

7 DR. WHITE: That is absolutely true,
8 except we heard today that many of these vein
9 grafts fail without symptoms or even very good
10 objective measurements. So, that is the problem.

11 DR. EDMUNDS: That can't be the only
12 criteria.

13 DR. TRACY: Dr. Zuckerman?

14 DR. ZUCKERMAN: The points that Dr.
15 Krucoff made about use of MLD instead of the
16 dichotomous endpoint of greater or less than 50
17 percent are very interesting, and also Dr. Bridges'
18 point about looking at the distribution of intimal
19 hyperplasia, etc. because potentially those
20 endpoints can decrease your sample size, but the
21 challenge that we have right now, until we learn
22 more about what that means, is to choose a patency
23 endpoint that is clinically relevant and that is
24 why we, at the FDA, like Dr. White's idea of the 50
25 percent benchmark right now. But, Dr. White, can

1 you explain that the actual determination of that
2 50 percent benchmark is very dependent with vein
3 graft disease on how you measure it, and do you
4 have any qualifying factors here?

5 DR. WHITE: Yes, I would like to be the
6 core lab!

7 [Laughter]

8 Bram is referring to the problem of what
9 is the reference object and what is the reference
10 segment from which you take the 50 percent diameter
11 in a vein graft. There are obviously differences
12 in the proximal and distal diameter of that graft
13 and that would have to be codified. I think you
14 would maybe even have to divide the graft into
15 thirds, as we used to talk about, proximal,
16 mid-body and distal regions of the graft, and we
17 could codify the nearest normal segment of that
18 graft to be the 50 percent measurement. The
19 problem with that is the ostium and then you would
20 have to take the nearest distal segment, which is
21 obviously a different standard.

22 DR. EDMUNDS: Why do you seek a single
23 outcome? My car fails in lots of ways--flat tire,
24 motor stops, clutch falls off, all kinds of ways.
25 So, if this proximal anastomosis blows off the

1 aorta, that is a failure as far as I am concerned.

2 DR. ZUCKERMAN: Right. If I were to
3 summarize your comments before, I think we agree
4 that all the endpoints that you noted must be
5 measured and observed on the case report forms.
6 One could generalize them into acute procedure
7 success composite variable and chronic success
8 composite variable measured perhaps at six months,
9 and the six-month variable would include that
10 measurement of greater than 50 percent patency plus
11 perhaps B or C, but I think the 50 percent patency
12 that Dr. White is referring to is a very important
13 part of that chronic composite endpoint due to its
14 clinical implications. It is where he would
15 reintervene if it was greater than that, which is
16 what we are interested in.

17 DR. BRIDGES: The other reason for the 50
18 percent is that the Fitz-Gibbon criteria are based
19 on 50 percent and there is a large literature so to
20 compare the data to that, obviously that would be a
21 useful endpoint and several recent studies have
22 used that classification system. So, clearly, it
23 would be important to have that particular cut-off
24 point.

25 DR. KRUCOFF: The only pitfall I would be

1 wary of then is if a 45 percent stenosis at 6
2 months is a harbinger of a 95 percent stenosis at
3 18 months, the dichotomous approach, if your
4 angiographic endpoint is too early, might create a
5 pitfall. I would just be thoughtful about
6 combining the timing of your angiogram--if a
7 primary endpoint is dichotomous at a clinical
8 level, to make that the timing of your angiogram is
9 sufficiently latent in natural history that it is
10 appropriate.

11 DR. ZUCKERMAN: Again, Dr. Krucoff, you
12 have given an analogy of the stent trials and you
13 mentioned first in man. Does part and parcel of
14 this need to be to show chronic stability in a
15 smaller subset between one and two years, which was
16 the first in man stent analogy? Another technique
17 that we used in the stent trials is to ask for an
18 IVIS subset study in order to show actual healing
19 at the site of implantation. Would you like to
20 comment?

21 DR. KRUCOFF: I think that is a little
22 tougher only because now you are really
23 instrumenting this. I think there has already been
24 expression of concern about how far you are going
25 to go with invasive procedures. I think it is

1 pretty compelling in this arena. You are going to
2 have to go at least to an angiogram. That is my
3 personal opinion.

4 I feel a little differently when it gets
5 to full anticoagulation in order to put an
6 interventional catheter, you know, a guide wire
7 through the vessel and bring a device down where
8 you are not actually planning therapeutic for the
9 vessel. It is possible that at a later time you
10 might eventuate a specific question to ask, Bram,
11 but I would be concerned about
12 over-instrumentation.

13 DR. HIRSHFELD: To follow-up on what Mitch
14 just said, the more I listen to this the more I am
15 concerned about the challenge of recruiting
16 subjects to participate in this trial. I am not
17 backing away from the importance of doing the
18 trial, but I think the challenge to the sponsors
19 and to the investigators will be to recruit a
20 patient who is going to receive two saphenous vein
21 grafts, and tell the patient that one of those two
22 grafts will be treated with this new device and, as
23 a reward for participating in this study, they get
24 to have a cath at six months. So, it may be that
25 there will be relatively limited incentive in the

1 part of patients to actually sign up for this, and
2 it might be a real challenge to recruit for this.
3 I think we have to weigh that consideration in
4 addition to everything else.

5 DR. AZIZ: We could ask the professor from
6 Germany, he could probably give us some insight as
7 to how difficult it was to recruit patients. Could
8 you give us some insight on that?

9 PROF. KLIMA: Could you just repeat the
10 question for me?

11 DR. AZIZ: You know, there has been some
12 concern raised that if we stay with the strict
13 criteria and the patients need to have an angiogram
14 that they may not want to come into the study. Did
15 you have difficulty in recruiting patients into the
16 trial?

17 PROF. KLIMA: Not at all. I think you
18 have to real give the patient the information that
19 you are using a new system, and even though all
20 these devices had a CE certificate in Europe which,
21 you know, is some kind of approval from the
22 European governments, you have to make the point
23 clear that this is that we do not know how it will
24 react within the next six months, twelve months, or
25 whatever. So, we talk to the patients before we do

1 the surgery and I would say that 99 percent of the
2 patients agreed to be a part of the study.

3 DR. AZIZ: Also, were they sort of
4 favorably disposed to the angiogram?

5 PROF. KLIMA: Well, I think that really
6 depends on your study coordinator. I would say
7 more than 80 percent would say yes, they will come
8 back for an angiogram.

9 DR. TRACY: I think we have a lot of
10 history of having protocols where we have had to
11 ask patients to come back and do procedures that
12 clinically otherwise wouldn't have been indicated.
13 Either you can do it with a good coordinator or you
14 can't. If you can't, then you are not going to
15 have the patients enrolled in the study. I don't
16 think that that is our concern here. I mean, we
17 are trying to decide what the best design is.

18 DR. AZIZ: I think that question has been
19 raised a number of times as to whether if you told
20 a patient they are going to have an angiogram at
21 six months how easy to would be to recruit the
22 patients.

23 DR. TRACY: Well, if you can't, you can't.

24 DR. WHITE: I think that is a cultural
25 issue. Having practiced in a European country, I

1 can tell you that the American population reacts
2 differently than they do in Scotland and I am sure
3 that the German population, in their relationships
4 to their physicians, is distinct from the
5 relationship that we have in the United States and
6 I don't know that that translates very well.

7 DR. BRIDGES: I have one quick question on
8 the study design by the professor from Hanover.
9 Given that you hand-sewed half of the anastomoses
10 and you used the anastomotic device for the other
11 half, and your patients were all done on bypass I
12 believe.

13 PROF. KLIMA: Yes.

14 DR. BRIDGES: How did you decide which
15 graft to do first? Did you use side-biting clamp
16 for your proximal anastomosis for the hand-sewn and
17 then remove it and then do the Symmetry device, or
18 did you use the Symmetry device in the presence of
19 a cross-clam? I just wanted to know if at some
20 point you could provide those details because those
21 would be important details in terms of figuring
22 out--if the committee decided to follow that sort
23 of study design, those would be important details.

24 PROF. KLIMA: Yes, we did both proximal
25 anastomosis first under the side-clamping condition

1 because there are several techniques out there
2 which allow you to make a proximal anastomosis
3 without side clamping. However, this is pretty
4 difficult because you would have another device
5 which you need to make a proximal anastomosis. So,
6 we just side-clamped, made the proximal anastomosis
7 first and then, as a consequence, we did the distal
8 anastomosis depending on the target artery which
9 was selected for the Symmetry device or the
10 hand-sewn anastomosis.

11 DR. BRIDGES: You applied the Symmetry
12 device with a side-biting clamp in place?

13 PROF. KLIMA: Yes, we did.

14 DR. BRIDGES: Which is a little bit
15 different than the typical application in beating
16 heart surgery.

17 PROF. KLIMA: Yes, that is correct but you
18 can use the system also in an arrested heart
19 situation where you make your cross-clamp, for
20 example, and still have the opportunity to make a
21 shot with this device. The side-clamp technique
22 allows you to have a pretty similar situation at
23 least for your first shot when you are doing the
24 Symmetry anastomosis because the aorta is still
25 filled with blood so you are able to bring the

1 system in, in a very similar way as you would do
2 without side-biting or without cross-clamping the
3 aorta.

4 DR. AZIZ: Did any of the patients have a
5 stroke?

6 PROF. KLIMA: No.

7 DR. TRACY: Dr. Hausen?

8 PROF. KLIMA: May I just make one final
9 comment because there was a lot of discussion going
10 on about this Hanover model I presented today, and
11 a lot of discussion going on with respect with
12 should we use historical controls, yes or no. I
13 think we cannot exclude historical controls because
14 if we just look at the Hanover data with hand-sewn
15 anastomosis compared with an automatic anastomosis
16 and if our hand-sewn anastomosis would have been as
17 bad as the Symmetry anastomosis, we would have
18 concluded that the Symmetry device is as good as
19 the hand-sewn anastomosis, which is absolutely not
20 comparable with this data of the atrial
21 vascularization. So, you have to have a historical
22 control in order to see whether your results really
23 compare to the data of the atrial vascularization
24 out there.

25 DR. TRACY: Thank you. Dr. Hausen?

1 DR. HAUSEN: Bernard Hausen. I share Dr.
2 Hirshfeld's concerns. If you look at all these
3 trials that are happening with these devices, 90
4 percent are done in Europe for a good reason,
5 because you can't recruit American patients to come
6 back and have their angiograms performed at six
7 months or, if you do, you get completion of
8 follow-up of less than 50 percent which Dr.
9 Zuckerman told us is not acceptable. I mean,
10 almost all these trials for American products for
11 American approval are done overseas. I think that
12 is an ethical concern, especially now that there is
13 a class action suit against one of the major valve
14 companies because one of the valves didn't work
15 well and the patients didn't fare well, and now the
16 lawyers in Europe are saying you are putting our
17 patients through all this for the benefit of
18 Americans because we think of all these wonderful
19 trials that involve lots of controls and follow-up.
20 So, I think that is just something we have to put
21 in context here.

22 DR. WHITE: That is not true. That is
23 absolutely not true. I mean, the European trials
24 clearly precede the American trials, that I won't
25 argue, but we do randomized trials; we do

1 angiographic follow-up at a very high percentage
2 rate for stent trials for example. So, we do the
3 same thing in the American population that we do in
4 the European population. It just usually lags
5 because of regulatory issues.

6 MR. MORTON: To echo Dr. Klima's very good
7 point, he has been conducting studies against
8 devices which are CE marked, that is, cleared for
9 marketing, and what we are wrestling with on the
10 panel today is what sort of information do we need
11 before going to 510(k) clearance and that very much
12 affects the sponsors.

13 MR. LOTTI: My name is Richard Lotti. I
14 am the CEO of Converge Medical. I have some
15 inherent conflicts, of course.

16 I just want to comment on the last
17 statement regarding trials in the U.S. We are one
18 of the companies that actually did attempt an IDE
19 trial in the United States. We have been
20 successful with it. I will tell you that we had 17
21 IRB sites approved in the U.S. Over a 12-month
22 period we were able to get 6 sites to enroll
23 patients. During a 3-month period in Germany we
24 were able to get 3 sites to enroll the same amount
25 of patients. So, there clearly are differences in

1 the two marketplaces, but we believe we have been
2 able to accomplish patients from both geographic
3 centers.

4 DR. TRACY: Dr. Blumenstein, I think you
5 have some analysis for us.

6 DR. EMERY: May I make one comment while
7 he is coming up? Dr. Klima raised a very important
8 point in technique because he put the Symmetry
9 device on while a partially occluding clamp was on.
10 I think that is a technical mistake and I am sorry
11 respectfully to do that, but you have to
12 depressurize the system to punch it. You apply the
13 device and then you repressurize the system to
14 aortic pressure and that can disrupt the seating of
15 the device and cause device failure. I think the
16 device was made to be applied in a pressurized
17 system, and varying from that developmental
18 indication can cause problems with the device. So,
19 it may not be a device failure that he suffered
20 through in his bad results but a technical
21 application of the device which alters the way it
22 is implanted.

23 DR. BLUMENSTEIN: Please keep in mind
24 these are very preliminary, cone by the seat of my
25 pants as I was sitting there.

1 [Slide]

2 So, one of the designs we discussed was a
3 paired comparison with a dichotomous outcome. Of
4 course, in any trial one must always identify a
5 primary outcome and in this structure one would
6 define a primary outcome for each vessel graft in
7 each patient and that would be a success or
8 failure. The success, for the purposes of this
9 presentation, is that the graft is okay at the
10 specific follow-up time, say six months. And, you
11 have to define what "okay" is somehow or another
12 and that, of course, is never simple. Failure is
13 not success and that is a way to try to get around
14 missing data but there are still some things I want
15 to say about that.

16 Within each patient you would randomize
17 two vessels or I suppose four if you could. If you
18 did that, then you have to consider whether you are
19 counting the patient as two units or one. It may
20 require special statistical techniques to handle
21 that situation but for the moment let's assume that
22 we are doing two vessels per patient. One would
23 get usual care, whatever that is, the other would
24 get the experimental intervention.

25 We have to decide also what to do about

1 inevaluable patients, that is, patients who don't
2 return for their, say, six-month evaluation. That
3 may not be so bad since you are missing both
4 endpoints but you would, of course, have to assess
5 the reasons the patients didn't come back.

6 There are lots of complications here. I
7 think I tried to communicate that before. This is
8 a very complicated design. It would be very
9 difficult to administer the randomization, and so
10 forth, and I think we already heard some other
11 people commenting on that. Nonetheless, it might
12 be worth trying.

13 [Slide]

14 The basic data structure is a 2 X 2 table.
15 What we would be recruiting would be N pairs of
16 vessels. For each pair of vessels there is an
17 outcome that is either failure-failure,
18 success-success, failure-success or
19 success-failure. So, each of these Ns represents a
20 number of pairs of vessels for which there is both
21 fail, both succeed, etc.

22 The outcome measure of interest is this
23 number here over this N and this number here over
24 this N, and specifically the difference between
25 those two proportions, that is, this over N and

1 this over N.

2 [Slide]

3 So, these two proportions estimate
4 proportion of success and control vessels and
5 experimental vessels respectively. The statistical
6 test one uses for this is called the McNemar test
7 for testing the difference in these proportions.
8 The required study size depends greatly on the sum
9 of N failed-success and N success-failed, in other
10 words, the discordant cases. If we go back, it is
11 these cases here that represent the difference in
12 outcome within the same patient. Specifically, a
13 smaller proportion of discordant cases leads to a
14 smaller study size.

15 [Slide]

16 Now I want to say a word about
17 non-inferiority because that is really I think what
18 we are aiming to test here. We would be testing a
19 null hypothesis of a specified difference. In
20 other words, we would beforehand decide what
21 represented non-inferiority. The alternative
22 hypothesis would be equal or better than
23 inferiority. Rejection of the null hypothesis
24 provides evidence of non-inferiority. I don't
25 happen to have software for planning a

1 non-inferiority trial for the McNemar test but we
2 can come close to that.

3 [Slide]

4 I want to say a word about data monitoring
5 in a non-inferiority trial. A data monitoring
6 committee watches for evidence of rejection of the
7 null and would also look for futility. But early
8 evidence of rejection of the null is easy if the
9 experimental intervention is superior. So, one
10 would put a non-inferiority trial under very tight
11 monitoring if one suspected that there was a
12 possibility of superiority.

13 [Slide]

14 The study size computed here is computed
15 for a specified difference of superiority. The
16 non-inferiority study size would be slightly
17 larger. I am sorry, I don't have the software for
18 that. I have assumed an alpha of 0.025 one-sided
19 and a beta of 1.0 or 90 percent power. That is
20 pretty rigorous. I decided to put in the delta,
21 that is, the difference that represented the
22 clinically consequential difference here, of 5
23 percent.

24 Now, these are different levels of
25 discordance. That is, this is the proportion of

1 total patients that are discordant at the end of
2 the trial. So, if we had 20 percent discordant
3 patients the total number of pairs of vessels would
4 be 845. If the discordance was only 10 percent,
5 you are down to a trial size of 420. I personally
6 don't know where in here you would be, or if you
7 were higher or even lower. That is something that
8 would have to be gotten from some other data.

9 [Slide]

10 I also did a two-group trial. Being
11 basically a refugee from cancer, I like failure
12 time endpoints so I designed this for a failure
13 time endpoint. Specifically here I said
14 intervention failure-free survival. I just called
15 this AOK. That is alive and okay. You would
16 assess this event continuously or as often as the
17 patient is evaluated immediately post surgery up to
18 whatever is decided to be a reasonable follow-up
19 time.

20 In particular, you might specifically have
21 time to evaluation, say, at six months as a major
22 evaluation. But the event is a reintervention or
23 death, whichever comes first. Hopefully, you
24 wouldn't reintervene after death. Anyway, this
25 requires a very careful definition of failure.

1 And, we are designing this again as a
2 non-inferiority trial. I am using an alpha of
3 0.025 one-sided, beta of 0.9.

4 [Slide]

5 If I assume that the proportion of
6 patients in the alive and okay at six months is 75
7 percent, and just from the data I saw before here
8 in the room that seems like that might be a little
9 low but perhaps not unreasonable considering that
10 we are talking about all kinds of failures, not
11 just failure of the patency of the vessel or
12 occlusion, whatever. So, this is what our control
13 arm would have.

14 Then we are going to assume that what
15 represents inferiority is a hazard rate, that is a
16 rate of failure that is 20 percent higher than in
17 the control arm. What I get when I do my
18 computation is 1,800 total patients required,
19 randomized in two groups.

20 [Slide]

21 Just to give you an idea of what this
22 looks like, this is patients--

23 DR. WHITE: Are those patients or vessels?

24 DR. BLUMENSTEIN: Paired
25 vessels--patients.

1 DR. TRACY: Patients or vessels?

2 DR. BLUMENSTEIN: Patients, each patient
3 contributing two vessels. So, assuming an
4 exponential distribution, which isn't quite right
5 because I doubt that your failure at two years is
6 this high so if I were going to do this outside the
7 context of this meeting I would probably use a
8 different distribution that would have a plateau
9 here. But we are focusing on this area here, not
10 out here. So, it is going to make a little
11 difference.

12 The black line represents the control arm.
13 The blue line represents what we consider to be
14 inferiority. The red line represents the critical
15 outcome, assuming the black line is true, of what
16 we would reject and where we would reject given
17 that outcome. So, that gives you an idea of what
18 the inferiority trial would like. You would be
19 looking at this definition between the black and
20 the blue line as representing the criterion for
21 inferiority, but the red line would be the critical
22 outcome assuming the control arm was actually
23 realized. That is it.

24 DR. HIRSHFELD: Dr. Blumenstein, one
25 generic question about this, for your AOK 75

1 percent rate I assume that you are looking at a
2 composite rather than a single endpoint. In other
3 words, any one of these trials to generate a 75
4 percent AOK rate as opposed to a 90 percent AOK
5 rate, we would be looking at a composite endpoint.
6 As a statistician, how do you feel about the use of
7 a composite endpoint as opposed to a single
8 endpoint for analysis?

9 DR. BLUMENSTEIN: Well, I think it makes a
10 lot of sense in this case because you don't know
11 all the reasons why you would want to discount the
12 experimental intervention. In other words, there
13 could be things happening that you did not
14 anticipate as a result of side effects, and so
15 forth. So, by using a composite endpoint of
16 failure, just simply failure, then you sop up all
17 those bad things that happen that you didn't
18 anticipate. In fact, if you think about it, this
19 is what counts to the patient also. So, the
20 two-group trial has the advantage of pulling
21 together all of those things. It focuses on
22 differences between the groups, whereas the matched
23 study is focused on success with respect to the
24 outcome in the vessels.

25 DR. HIRSHFELD: Right, although in the

1 interventional world a composite endpoint has been
2 criticized because some of the components of the
3 endpoint are subject and involve clinical decisions
4 and there is varying of actual clinical
5 significance, and this has led to a great deal of
6 consternation in the interventional arena in terms
7 of the meaning of the composite endpoint that gets
8 virtually into all the interventional device
9 trials.

10 DR. BLUMENSTEIN: Yes, I mean this is the
11 reality. One would think about setting up an
12 endpoint committee to review the declaration of the
13 endpoints, the timing of them and so forth. I
14 mean, this is not uncommon throughout all of
15 clinical medicine to be discussing endpoints that
16 require some kind of judgment. At least with
17 time-to-event, given that you don't have a lot of
18 issues with respect to interval censoring, that is,
19 frequency of follow-up and so forth, I think you
20 have a gain in precision of using it as a
21 time-to-event rather than as a binary outcome.

22 DR. BRIDGES: One other study design that
23 you didn't show us is what if we didn't have each
24 patient as their own control but you had two
25 separate groups of patients where, in each case,

1 all of the proximal anastomoses for example were
2 done with one device, and in the other case all of
3 them were done in the conventional manner, assuming
4 that you typically had two grafts per patient.
5 Would that result in fewer patients being required
6 or a greater number of patients being required,
7 particularly in view of the concerns that have been
8 raised by Dr. Emery regarding the Hanover study
9 design? If we backed up and went to a control
10 group that just had hand-sewn anastomoses and an
11 experimental group that had device implemented
12 anastomoses, how would those numbers work out in
13 that case?

14 DR. BLUMENSTEIN: Well, that was the
15 second design that I showed you. It would be
16 randomization to a group of patients treated by
17 usual care--

18 DR. BRIDGES: Sure.

19 DR. BLUMENSTEIN: --but I used an
20 outcome--

21 DR. BRIDGES: But you used a single
22 outcome.

23 DR. BLUMENSTEIN: Yes, I used an outcome
24 that represented time to failure in essence.

25 DR. BRIDGES: Right, but in this case what

1 I am suggesting is that you would actually have two
2 outcomes in each patient, the patency of each of
3 the grafts, which would I think decrease the number
4 of patients necessary. In other words, the total
5 number of data points would be twice the total
6 number of patients in that case, whereas, in your
7 study proposed the number of data points is equal
8 to the number of patients, that is, AOK or not AOK.

9 DR. BLUMENSTEIN: What you are talking
10 about is using a different endpoint than this
11 failure time endpoint, and using an endpoint where
12 you can have multiple observations of that endpoint
13 for each patient. That is a possibility but you
14 then get into issues about what happens if you have
15 missing on one and not the other, or if you have
16 three vessels in one patient and two in the other.
17 You get into some issues like that. They are not
18 difficult terribly but they do cause some kinds of
19 complications. One of the first things that
20 happens is you wonder if the patients who
21 contribute more vessels aren't the ones that were
22 sicker to begin with. So, you have a lot of those
23 kinds of issues. I mean, there are many, many
24 other trial designs that we can talk about.

25 I thought you were going to ask me about

1 whether there could be a trial design that had
2 multiple endpoints, for example not only occlusion
3 but also patency and other things of that nature.
4 There are trials that are designed to allow for
5 multiple endpoints, success being defined, say you
6 had five endpoints, meeting three of five. That is
7 a whole other ball game that is very complicated
8 and difficult to get into.

9 DR. EDMUNDS: That is what I was thinking
10 about, leaving out death because that trumps all
11 endpoints, but a composite endpoint of all of those
12 things that I listed. Is that feasible at all?

13 DR. BLUMENSTEIN: Well--

14 DR. EDMUNDS: And mapping that endpoint
15 meets every outcome within the composite having a
16 normal distribution, doesn't it?

17 DR. BLUMENSTEIN: Well, no, it depends on
18 what you are measuring. You are talking about
19 multiple things contributing to the definition of
20 failure where any one of them can cause a patient
21 to be declared a failure at that moment in time.
22 There is that, plus there is the multiple
23 measurements that one could do. You know, all of
24 these variations lead to different trial designs
25 and different considerations.

1 The problem that you have when you define
2 multiple endpoints, multiple distinct endpoints is
3 that then you have the weighting issue. Which
4 endpoint is more important than others? For
5 example, in arthritis trials they may have multiple
6 measurements of outcome and they always have the
7 issue of how you weight those things, what is more
8 important.

9 DR. EDMUNDS: But these cardiology trials
10 usually have death, myocardial infarction and
11 reintervention, or something like that, as a triple
12 composite endpoint. I have always wondered whether
13 that is statistically sound.

14 DR. BLUMENSTEIN: Oh, I think it is
15 statistically sound. It is statistically sound to
16 consider failure without death. The problem is
17 that you have a hard time making a Kaplan-Meier
18 curve in that case because the Kaplan-Meier curve
19 is them--

20 DR. EDMUNDS: But death trumps. I would
21 much rather have a myocardial infarction than die.
22 So, they are not equal endpoints and, yet, they are
23 rolled together as a single outcome.

24 DR. BLUMENSTEIN: Yes, but they make sense
25 to the patient. That is, the patient wants to live

1 without reintervention so that endpoint as a
2 composite makes sense as a definition of patient
3 benefit. Usually in a trial where you have a
4 composite endpoint you feature as secondary
5 endpoints subsets of events that make up the
6 composite.

7 DR. EDMUNDS: Well, if it works for
8 cardiologists why doesn't it work for surgeons?

9 DR. BLUMENSTEIN: Well, I don't know why
10 it wouldn't. I think it would.

11 DR. TRACY: I think we are sort of
12 addressing question number four, which is should
13 the primary effectiveness endpoint be graft patency
14 alone, or include both graft patency and myocardial
15 perfusion? I think we are looking at trials that
16 are quite large at this point, with a minimum of
17 420 and a maximum of 1,800 patients, looking at
18 very hard endpoint. I think we would need to try
19 to fine-tune that and see if there really are
20 additional effectiveness endpoints that make some
21 sense in this context so we are not studying
22 devices ad nauseam. Chris?

23 DR. WHITE: I thought that was great.
24 That was one of the few times I could understand
25 what a statistician has to say, and I think those

1 numbers are way too big--way too big. I think they
2 are not realistic. I think that is not what this
3 field is used to. I think I would be happy with
4 smaller studies that would satisfy the need and I
5 think we need to come up with ways to make these
6 trials doable in order to provide us with useful
7 information.

8 DR. BLUMENSTEIN: You are the first
9 physician who has ever said to me that they prefer
10 a smaller trial. I am amazed.

11 [Laughter]

12 We statisticians are always in the role of
13 trying to get you to do more than you want to do.

14 DR. WHITE: I just think that when you
15 look at 400 patients in a trial like this, that is
16 bigger than any trial I can think of, perhaps not
17 drug trials but when you talk about device trials
18 and surgery trials a couple of hundred patients is
19 huge. So, 1,800 is out of the question; 400--I
20 heard four people hit the floor over there; they
21 passed out.

22 MR. MORTON: It is not so much that anyone
23 wants smaller numbers, we would love to bring
24 larger numbers to the FDA but it is the
25 affordability of the trial.

1 DR. WEINBERGER: Just one comment, that is
2 something on your slide about the exponential
3 drop-off rate. That is, the earlier you look after
4 the time of implantation, the larger the sample
5 size you will need to show a small difference. As
6 time develops from the original implantation the
7 two curves should splay apart further and one
8 should be able to do the trial with smaller
9 populations to show a meaningful difference. Is
10 that correct?

11 DR. BLUMENSTEIN: If you are talking about
12 the same difference but at a later point in time,
13 you actually need more patients. The other aspect
14 of this is that there are other causes of graft
15 failure than failure of the proximal connector, and
16 the longer you wait the more those causes come into
17 play and become essentially noise in the data set.

18 DR. BRIDGES: So, do I interpret Dr.
19 Blumenstein's analysis to suggest that a randomized
20 trial to look at either a composite endpoint or
21 graft patency, certainly in the paradigm of the
22 patient serving as his own control, would require a
23 larger number of patients than we think is
24 appropriate? Then, does that imply that we should
25 take a step back and go to the historical control

1 issue? Also, as an aside, do you agree with Wolfe
2 Sapirstein's calculations about the number of
3 patients, which is considerably less, that would be
4 required if we use the historical measures such as
5 80 percent patency for vein grafts and 95 percent
6 patency for mammary grafts?

7 DR. BLUMENSTEIN: I mean there is nothing
8 wrong--I didn't redo the computations. I assume
9 that the computations were done correctly.

10 DR. ZUCKERMAN: They were done several
11 times.

12 [Laughter]

13 DR. BLUMENSTEIN: But we are using
14 completely different methodologies, different
15 criteria and so forth. They are not completely
16 comparable. But I think the main difference is
17 that the computations shown earlier were based on a
18 single group non-inferiority assessment which
19 suffers from all of the things that one would
20 suffer from by using retrospective data,
21 non-concurrent, randomized controls that is.

22 So, I think it is very important to first
23 decide whether it is essential, and I think it is
24 personally, to have randomized to control for all
25 of these factors that you can't control and can't

1 measure and then go on from there. I also want you
2 to remember, and I tried to point this out as I was
3 showing those slides--I was trying to give you an
4 upper bound on the sample sizes. I was using 90
5 percent power, and so forth, and it is possible
6 that you can trim the sample sizes some. Also, I
7 chose criteria, you know, based on the things that
8 I have seen here today and my best guess at it. It
9 may be that I am using criteria that are too tight.
10 I don't know but this is a beginning.

11 DR. TRACY: Dr. Edmunds?

12 DR. EDMUNDS: Would it be irrational to
13 consider any of this list an adverse event and then
14 calculate the number of adverse events for each of
15 the two groups randomized prospectively, and do a
16 power calculation for the occurrence of any one of
17 several adverse events, one per patient maximum,
18 and compare the two at a certain time point? Could
19 that get our N down, and a 5 percent difference
20 rather than 10 or 20? Because we are trying to
21 show equivalency.

22 DR. BLUMENSTEIN: Well, that is the reason
23 I showed you the two-group non-inferiority trial.
24 In point of fact, the things that went into the
25 definition of what I called AOK could be adverse

1 events, that is, things that I
2 said--reintervention, that was just a suggestion.
3 You could say that the definition of failure is
4 anything bad that happens, in which case it becomes
5 time to first bad thing. But, you see, in order to
6 preclude the kind of inferiority that I used in
7 those computations, it requires a fairly large
8 trial size.

9 DR. EDMUNDS: So, the first model was just
10 chi square, wasn't it?

11 DR. BLUMENSTEIN: It is a McNemar--yes, it
12 is a chi square.

13 DR. TRACY: I think if you really have an
14 inferior product, by one of these methods you are
15 going to pick it up quicker but if you have
16 something that is not inferior it is going to take
17 longer and it is going to require larger patient
18 populations, and I think there really is an issue
19 here of what is feasible to do; how many patients
20 is it reasonable to include? These are massive
21 trials that we are talking about. I think we
22 either have to come up with a better answer to
23 number four, looking at primary effectiveness, or
24 we have to readdress the idea of historic controls.

25 DR. BLUMENSTEIN: I want to emphasize that

1 the two trials that I presented are really quite
2 different in terms of their objectives.

3 DR. TRACY: Right.

4 DR. BLUMENSTEIN: They are quite
5 different.

6 DR. TRACY: Right. I don't think we got
7 an answer here but I think we see what the problems
8 are.

9 DR. HIRSHFELD: We can answer this
10 question though, can't we?

11 DR. TRACY: Number four?

12 DR. HIRSHFELD: Yes. I mean, it is
13 patency, period, isn't it?

14 DR. TRACY: Number four is should the
15 primary effectiveness endpoint be graft patency
16 alone, or include both patency and myocardial
17 perfusion? I think we have heard that myocardial
18 perfusion doesn't necessarily predict patency. I
19 think patency is a definite primary endpoint. I
20 would think that primary effectiveness is going to
21 in part depend on how large the trial has to be.
22 If your trial has to be enormous, they you accept
23 other pieces of primary effectiveness.

24 But I think that patency as the
25 dichotomous thing--it is either open or it is

1 not--is a very important endpoint but the other
2 criteria, such as aortic complications, neurologic
3 changes, hemorrhagic problems, acute revision, all
4 those are other primary effectiveness endpoints in
5 particular for the proximal anastomoses. So, I
6 think you look at your specific device and decide
7 whether there are specific primary effectiveness
8 endpoints that you need to reach. If you are
9 having a 30 percent aortic dissection rate with
10 this particular device, then it is a real problem.

11 DR. EDMUNDS: I would argue for any
12 adverse event compared between the two groups, and
13 if we find that the adverse events are similar
14 between the two groups then the new device is no
15 worse than what we are doing now, and that really
16 is the question.

17 DR. WHITE: I disagree. I mean, I
18 understand what you mean but I disagree. I think
19 the endpoint is patency. In fact, the primary
20 endpoint has to be patency; the secondary endpoints
21 can be other issues. But I think the trial,
22 whatever we look at, has to be powered at patency
23 because the experimental device has a direct effect
24 on patency of the graft and that is what we care
25 about.

1 DR. HIRSHFELD: After all, we are going to
2 measure patency by a fairly sophisticated
3 technique, i.e., angiography. These others are
4 going to require endless hours because they are a
5 continuum. You know, you have good flow; you have
6 bad flow.

7 DR. EDMUNDS: Yes, but nobody learns
8 anything if the trial is not done because it is so
9 large.

10 DR. TRACY: If we can move on to number
11 five.

12 DR. ZUCKERMAN: I think we forgot question
13 number three.

14 DR. TRACY: Oh, I am sorry. That is true,
15 we did skip that. Number three, do you believe
16 that the significant differences between an
17 arterial conduit and a venous conduit warrant
18 distinct study criteria and assessment for each?
19 If so, please identify these criteria and analyses.

20 I think the essence was yes, they are
21 different. They are distinctly different, however,
22 the endpoints of patency remain the same whether it
23 is a venous or an arterial structure we are talking
24 about.

25 DR. ZUCKERMAN: Well, then this helps both

1 the agency and the industry develop a paradigm.
2 You are saying that a specific indication could be
3 developed for a device intended for the internal
4 mammary and a specific indication could be
5 developed for an SVG device, whether it is proximal
6 or distal, and they are two separate trials.

7 DR. TRACY: Yes.

8 DR. ZUCKERMAN: Then, the next question is
9 suppose we are talking hypothetically about an SVG
10 device, the circumflex vessels may behave
11 differently than right-coronary artery. So, what
12 type of distribution or other advice can you give
13 to allow us to have confidence that we don't have
14 to keep slicing and dicing, that we have enough
15 data. Should we have 50 percent RCA, 50 percent
16 circ, or is that too proscriptive, etc.?

17 DR. WHITE: I think that is too
18 proscriptive. Why doesn't it work to do what we do
19 for stents, and that is that you get data from a
20 stent trial that you then retrospectively look at
21 LAD, circumflex and right because you know there
22 will be a distribution of those? We know from
23 those large trials what the distribution would be.
24 So, I don't know if there is a priori any reason to
25 consider a difference between circumflex and a

1 right graft. I am not aware that there are
2 differences in patency there. But I would simply
3 do that in a retrospective way, assuming that there
4 would be a good population of patients having both
5 of those grafts done.

6 DR. EDMUNDS: If you are insisting on
7 patency as the only primary endpoint, you are
8 trying to make this a stent trial and not a
9 surgical trial of an anastomotic connector. And,
10 this is a surgical trial of how to make a
11 connection. It isn't a stent trial and the analogy
12 is not very good. That is why I think there are
13 multiple adverse outcomes and I don't think you can
14 ignore the others just to concentrate on 50 percent
15 or greater patency.

16 DR. ZUCKERMAN: In general I think the
17 agency would agree with that viewpoint. Even if
18 the sponsor wins on patency but the aortic
19 dissection rate or neurological complication rate
20 is unacceptable, then it is an unacceptable device.
21 We would ask the sponsor up front, even though one
22 of the key sample size calculations would be for
23 the patency hypothesis, to show with what
24 confidence they can rule out some of these other
25 problems because we are looking at multiple key

1 endpoints. But I guess the question that I have
2 for number three is, is there a big difference
3 between plugging in these grafts with devices to
4 the circ and RCA territories up front that we
5 should be very proscriptive in terms of number of
6 vessels or, as Dr. White has suggested, if you get
7 a fair distribution and then retrospectively it
8 looks like the results are homogeneous, then that
9 is okay?

10 DR. MAISEL: I think it is one of the
11 factors that goes in with all the other preclinical
12 factors--presence or absence of diabetes, the
13 distal outflow of the graft. I think which vessel
14 it is attached to is equivalent to one of those
15 other factors.

16 DR. HIRSHFELD: I agree with that. I
17 think that path is an endless path and if you have
18 a hard data point--I agree with Chris, if you have
19 a hard data point that is our goal you can pick up
20 all those other things on an analysis of the data.

21 DR. EDMUNDS: I think we need to remember
22 that these surgeons are not using these vein grafts
23 to go to the LAD, and there are plenty of people
24 walking around asymptomatic with a patent LAD and
25 nothing else. It is the most important they are

1 grafting the right and the circ with occasional
2 diagonal branches. We need to consider this in the
3 trial and I think you have to consider multiple
4 endpoints because we have multiple complications
5 which are unique to this device, or so it is
6 alleged.

7 DR. ZUCKERMAN: Right, and I think we
8 would like other panel members to respond. I think
9 we are in agreement that we are going to consider
10 multiple endpoints but I like your other point that
11 you just made about the importance of LIMA patency
12 for prognosis and survival. Then the implication
13 is if we are looking at separate trials for the
14 LIMA devices versus the SVG devices, are you
15 implying that our delta for non-inferiority for the
16 LIMA trials should be much tighter, say, than for
17 the SVG trials?

18 DR. HIRSHFELD: I would like to respond to
19 that. I would like to find out first who in the
20 room would have the intestinal fortitude to do a
21 mechanical device LIMA to LAD? I mean, that is the
22 gold standard. I agree with him that there are
23 people running around, myself included, that have
24 LAD grafts that have been patent for 20 years. To
25 say that somebody is going to put a device in there

1 I think is absolutely wrong. I mean, I would make
2 a condition of the instruments that they exclude
3 the LAD-LIMA.

4 DR. TRACY: We will take a comment but we
5 are rapidly going to be losing panel members here
6 so if we can try to move along here.

7 MR. FOLEY: I will try and address that
8 question. I am Mark Foley. I am CEO of Ventrica.
9 Actually, in the trial that we just completed,
10 which was a 100 patient trial with six-month
11 angiographic follow-up, core lab-assessed data and
12 a clinical events committee looking at the MACE
13 endpoints in the trial, we did do LIMA-LADs. We
14 had a 94 percent patency rate in LIMA-LAD. We also
15 did one-year clinical follow-up on the same group
16 of patients. In that group of patients that we
17 followed 46 of 48 were contacted; two were not able
18 to be reached. We had no additional events, no
19 admission to hospital for chest pain, no
20 reoperation, no additional caths in that group.

21 DR. HIRSHFELD: I think that is terrific
22 but I think you have to follow those people 20
23 years because the gold standard, as you well know,
24 is LIMA to LAD hand-sewn.

25 DR. KRUCOFF: Did you have any trouble

1 enrolling patients?

2 MR. FOLEY: We didn't. Our trial was done
3 completely in Europe so we were able to enroll
4 patients in the trial. But I would like to ask one
5 more question to Dr. Zuckerman's point, with
6 mammary graft patency will we need to do a separate
7 trial for vein grafts?

8 DR. TRACY: I am not sure what the answer
9 to that is. I think we are struggling here because
10 the behavior of the vessels is different and the
11 LIMA to LAD is considered the best patency rate
12 that we have. Dr. Aziz, do you have any answer for
13 us?

14 DR. AZIZ: I think you have said it. I
15 think the biology--you know, the arterial grafts
16 produce prostacyclin and there are a lot of other
17 factors that keep pushing down there so I think at
18 this early stage you should consider them
19 differently. Once you have the data, then I think
20 maybe in the future we may not need to. But at
21 this stage we don't know how the reaction to injury
22 is going to be with some of these new devices.
23 Even though you have shown it is good in the
24 arterial circulation and anastomosis I still think
25 you need to look at it differently.

1 MS. WOOD: I think I am going to have to
2 insist that we move on to the next question because
3 we are going to lose panel members. We have two
4 more questions to discuss. Let's please make them
5 as brief and to the point as possible for comments,
6 please.

7 DR. TRACY: Number five, with regard to
8 device safety what criteria, i.e., acceptable
9 adverse event rate, as compared to that for suture
10 should be applied to the evaluation of device
11 safety as distinguished from device effectiveness,
12 for example, myocardial infarction, reoperation,
13 neurologic events and incidence of aortic
14 complications?

15 DR. EDMUNDS: What is the difference to
16 the patient from a huge stroke? I mean, I don't
17 see the distinction between safety and
18 effectiveness here. Effectiveness, you could
19 argue, is patency but safety is just about
20 everything else.

21 DR. TRACY: I think safety is, for
22 example, the device ripping off the aorta as the
23 patient stands up the first day postoperatively
24 versus effectiveness, finding a vessel six months
25 out to be patent. So, I think there are some

1 different safety versus effectiveness endpoints but
2 I think that they should be basically the same
3 safety and effectiveness endpoints as a suture
4 anastomosis would be expected to have. So, I don't
5 think there is a difference between those two
6 safety and effectiveness endpoints.

7 DR. KRUCOFF: Again, another way to
8 approach this is to start with what is the primary
9 question and what is that going to power to versus
10 what are all the other key concerns about lower
11 incidence events that could happen, and how broad a
12 boundary around those events also would influence
13 thinking about power. You can separate out for a
14 given question a primary endpoint that is
15 effectiveness versus an adequate assessment of
16 safety.

17 DR. YANCY: And it could be that the
18 better way to do this so we don't struggle is use
19 it as a time-related function, so have group safety
20 and efficacy in one bundle and look at early and
21 then intermediate. That would probably suffice to
22 capture the spirit of the question.

23 DR. SAPIRSTEIN: Can I just make one
24 point? We make a distinction between safety and
25 effectiveness and it may not be a very hard

1 distinction, but if we have to re-explore a patient
2 for bleeding and put an extra little stitch in,
3 that is a safety event. If the patient develops a
4 peripheral embolus from the device which still has
5 good patency and the patient gets an infarction in
6 the bed, we call that an adverse event that occurs.
7 Maybe this is not a realistic approach but from the
8 point of view of evaluating these devices we do
9 have to make a distinction between effectiveness
10 and safety.

11 DR. TRACY: It also becomes difficult to
12 use the patient as their own control because if a
13 patient goes back for a re-bleed for one thing
14 versus another thing, it doesn't matter to that
15 patient, they are still going back for a re-bleed.
16 So, that argues in a way for using historic
17 controls or randomization between a control group
18 and an experimental group but we are seeing that
19 that experimental group might be prohibitively
20 large.

21 DR. EDMUNDS: You know, if a device comes
22 loose from the aorta, is that effectiveness
23 failure? Is the device not effective? Absolutely.
24 Is it safe? Hell, no.

25 DR. TRACY: Right. We will move on to

1 number six, with regard to appropriate patient
2 follow-up, part a), in view of the possible
3 persisting risk of failure of some mechanical
4 anastomosis sites, distinct from progression of
5 native vessel disease, what duration of follow-up
6 is advisable for premarket evaluation?

7 I think we have sort of addressed these
8 issues. We don't know the biologic activity of
9 some of these things or exactly what the time frame
10 to healing is but we do have to come up with some
11 arbitrary point at which a look is taken, and that
12 might be six months, nine months, something that
13 could be concretely determined as the point at
14 which experience so far tells us that most of the
15 failures would have occurred in the devices that
16 are currently on the market. So, I think we can
17 look at that and decide what that time frame would
18 be for the repeat angio, which seems to be the
19 standard that we are leaning towards for a concrete
20 output.

21 DR. KRUCOFF: Again, beware of the pitfall
22 that if you look earlier you may see a sign that
23 may or may not be clinically relevant yet. So, if
24 you use a continuous measurement of lumen diameter
25 earlier, that will probably work. If you use a

1 cut-off, is this a flow-limiting lesion earlier, it
2 may not work and you may really miss something that
3 blossoms later.

4 The other option to wait until later, you
5 then have more clinical events that will accrue
6 before you look. So, I think you just have to be,
7 again, thoughtful about what is the intention of
8 the trial design as to where you put that and what
9 endpoint you are using, dichotomous or continuous.

10 DR. TRACY: But, again, in terms of study
11 design it does become difficult to ask a person to
12 come back in a year after an intervention. By that
13 time they have forgotten what you did in the first
14 place so they are not too likely to want to come
15 back. We are already wrestling with a pretty, you
16 know, task-full study.

17 DR. ZUCKERMAN: Dr. Tracy, I think you
18 have outlined the tensions in this question, but
19 the real question then is, is the stent model
20 applicable, as Dr. Krucoff just said, where
21 routinely there is six-month angiographic follow-up
22 but clinically the patients are followed for
23 another three months to make sure that something
24 seen on the angiogram which may not look
25 significant doesn't portend something down the

1 road. You know, is there a role for later clinical
2 follow-up?

3 DR. TRACY: I think we have heard from
4 some of the members that came to speak today that
5 further follow-up is warranted, whether that be by
6 phone follow-up or clinic visit. That probably is
7 appropriate at some point past the angiographic
8 follow-up.

9 Part b), should postmarket follow-up be
10 required to assess long-term device effectiveness?
11 If so, please define the appropriate length of
12 follow-up after primary patency evaluation.

13 I don't have a specific time but I do
14 think that out to a minimum of a year with some
15 type of clinical follow-up, whether that is phone
16 contact or office contact.

17 Number seven, can non-invasive measuring
18 instruments, example, echocardiography, ultrafast
19 spiral CT, MRA, EBT, etc., be used for primary
20 assessment of graph patency or is angiographic
21 follow-up necessary? And, at what time points
22 should patency be assessed? John?

23 DR. HIRSHFELD: I would like to throw out
24 a suggestion and to get the group to react to it.
25 I think there are three patency variables, acute

1 patency which is was the graft patent at the time
2 of hospital discharge and the major determinants of
3 that are likely technical. Then there is
4 intermediate patency, which is probably somewhere
5 between three and six months. Then there is late
6 patency, which is six months and beyond.

7 I would submit that non-invasive imaging,
8 either MR or CT angio, can answer the patency
9 question, and that we should reserve angiography
10 for the time at which we want a morphologic
11 assessment of the actual appearance of the graft.
12 So, one possible paradigm would be to obtain a CT
13 angio or an MR at the time of hospital discharge
14 which would establish the patency of the graft at
15 that point and we probably take technical and acute
16 thrombosis issues off the table at that point.
17 Then, intermediate patency at three to six months
18 could be assessed by another non-invasive imaging
19 study and that might identify candidates for an
20 early angiogram to try to delineate the etiology of
21 the graft failure when graft failure is observed.
22 Then, the late patency would be at six months and
23 that would be an angiographic study.

24 DR. KRUCOFF: One historical lesson
25 learned just to keep in mind, whenever your

1 angiographic endpoint is, we have certainly seen
2 that the threshold to reoperate is going to be very
3 high but the threshold to dilate or stent a 75
4 percent lesion in a completely asymptomatic person
5 once you are in the cath lab, judging by our own
6 history, is going to be very tempting. So,
7 recognize that if you put the angiogram early and
8 don't let people have events you are going to
9 generate events that go with the angiogram. I
10 would suggest that what you do for already
11 enrolling studies maybe we have to take another
12 half step back, but certainly for planning future
13 studies or until we understand the biology of these
14 things in the proximal and the distal locations,
15 which are different, I would suggest pushing out to
16 at least nine months and possibly even a year if
17 the investigators felt it was feasible to get
18 patients back.

19 DR. TRACY: Chris?

20 DR. WHITE: I agree with John. My only
21 reservation is that we are asking the non-invasive
22 technology to really step up here. I think that
23 probably those of us around the table who are not
24 absolutely confident that CT or MR is going to give
25 us--at least in our own hands and probably in our

1 own hospitals, we don't understand the same
2 reliability. But I think the early tests and the
3 screening that we are talking about, it is fine to
4 do it that way as long as the hard endpoint is done
5 with angiography. I think that Mitch is right that
6 late is better but if I was the investigator six
7 months would be where I would really be wanting to
8 do this because I think there is enough activity
9 there. I think we have heard today that the suture
10 lesions in the mammary had calmed down by six
11 months so those sort of things aren't going to be
12 there. And, I think that immediacy to the patient
13 is important. So, I would suggest the six-month
14 angiogram would be okay.

15 DR. YANCY: I think especially for the use
16 of a non-invasive variable early on, a core lab or
17 a central reading environment really is critical
18 since there is so much more subjectivity about that
19 interpretation.

20 DR. BRIDGES: Since we are talking about
21 analogies to the percutaneous coronary intervention
22 literature, what is the precedent for the use of
23 non-invasive imaging to assess not graft patency
24 but angiographic patency?

25 DR. WHITE: Well, in the coronary

1 circulation it is very early on, as you know. In
2 the peripheral circulation it is an acceptable tool
3 for looking at patency of non-coronary vessels.

4 DR. BRIDGES: But in the coronary because
5 that is what we are talking about?

6 DR. WHITE: If we are looking at grafts, I
7 think there is quite a literature about looking at
8 graft patency. I don't think it is unrealistic. I
9 just think that in your hospital you are not going
10 to say that your sensitivity and specificity is 94
11 percent because you haven't looked at that, and
12 most of us haven't in our own hospitals.

13 DR. TRACY: I don't think it is most of us
14 in our hospitals, I think nobody has. I just don't
15 think those are established techniques but I think
16 that they do have merit in a trial like this and as
17 an intermediate endpoint I think they are
18 appropriate. Dr. Sapirstein, is there something
19 else that we should be talking about here?

20 DR. SAPIRSTEIN: No, I think you have
21 helped us considerably and we appreciate that very
22 much. I know there are still a lot of
23 argumentative principles and debate but I think you
24 have given us considerable help.

25 DR. TRACY: Thank you.

1 MR. MORTON: Dr. Tracy, one quick comment,
2 back to 6 b), what we would be looking at in 6 b)
3 would be a postmarket--what the panel indicated was
4 that, yes, there would be some further information
5 that you would be interested in at, say, one year.
6 Postmarket surveillance usually is not done on a
7 510(k) device and what I would suggest is that
8 there could be some creative way of getting the
9 information that you would be interested in perhaps
10 by writing into the clinical protocol that there
11 would be telephonic follow-up, say, at one year,
12 but at the follow-up time of the study the data
13 could be compiled and submitted to the FDA with
14 that phone follow-up to follow. That way we stay
15 out of that unfamiliar regulatory field of
16 postmarket surveillance with a 510(k).

17 DR. TRACY: I think the spirit of what we
18 want to know is because the biologic activity of
19 these devices is not known, Dr. Krucoff and others
20 have indicated that the six-month look may be
21 premature in terms of finding the true failure rate
22 of these devices. Therefore, some additional
23 follow-up at some later point is appropriate. Now,
24 exactly where in the regulatory process that takes
25 place I am not clear, but I think you need to ask

1 the patient, "hi, how are you doing? Have you had
2 any chest pain?"

3 DR. ZUCKERMAN: Dr. Tracy, we are going to
4 clarify that regulatory process for you right now.

5 DR. HOANG: This is Quynh Hoang, from the
6 Office of Surveillance and Biometrics. I am from
7 the side that does the postmarket. To answer your
8 question, yes, it is possible to request a
9 postmarket surveillance study on even a 510(k)
10 device. The question that we would need is what is
11 the postmarket public health question that you have
12 for the device. It is not limited to the premarket
13 side of how the device was cleared or approved or
14 entered the market. So, I have to stress the
15 adjective or the qualifier of it being a postmarket
16 question, it should not be a question that is
17 required to be answered for the device to be
18 considered acceptable to enter the market. It is a
19 postmarket public health question.

20 DR. TRACY: I think we are looking for
21 late failures, late clinical failures. So, you are
22 asking the patient how they are; have they had
23 chest pain; have they required reintervention; are
24 they alive or dead.

25 MS. HOANG: With the question defined,

1 what we would do would be to go out and it is an
2 order from the FDA to the company to perform a
3 postmarket surveillance study. The one caveat for
4 such a study is that, by law, it is not typically
5 longer than three years. The other one is that the
6 company can come back--we pos the question but the
7 company can come back and offer us different ways.
8 It could be a registry; it could be continued
9 follow-up of the patients that were studied for the
10 premarket application. We would not be
11 prescriptive. We would not identify what study
12 needs to be done. It would be the role of the firm
13 to come back and say this is how we plan to do
14 address the postmarket public health question.

15 DR. MAISEL: I think that one-year
16 clinical follow-up prior to device approval is not
17 a huge burden given that we are doing a six- or
18 nine-month angiogram.

19 MS. HOANG: When you put in the statement
20 before device approval you have already cut out the
21 postmarket. This is a question that needs to be
22 addressed after the device already enters the
23 market.

24 DR. TRACY: But the spirit of why you are
25 doing it at any point, whether it is premarket or

1 postmarket--and I agree postmarket is appropriate
2 for these devices--is to find out whether there is
3 something you didn't anticipate. I think it is
4 certainly in the company's best interest to adhere
5 to that spirit of finding out whether their product
6 needs improvement. So, I don't see where they
7 would have any objection to a full type of
8 follow-up with very specific questions that really
9 deal with any unanticipated later outcomes.

10 MS. HOANG: Yes, the only caveat again is
11 that it should not be something that you would need
12 to know before you clear the device because it is a
13 postmarket study.

14 DR. TRACY: Right, and I think that is why
15 we have to be careful in making sure that our
16 concrete endpoint is at a point where we are
17 comfortable. Even though there is biologic
18 variability, I think we have to just say, given the
19 difficulty in getting patients to come back, we
20 have to accept a six-month invasive follow-up
21 point. Then the postmarket surveillance would be
22 for other unanticipated things to be caught at that
23 point.

24 DR. BRIDGES: Just a point of
25 clarification, I thought that if a device is

1 approved under the 510(k) it is either approved or
2 not approved. It can't be approved with a
3 condition based on a postmarket survey. Is that
4 correct?

5 DR. ZUCKERMAN: I think what you heard is
6 that there should be sufficient data in the
7 application to be able to make a clearance
8 decision. In other words, the major data should be
9 in the application. But then, if there are certain
10 persisting questions or a chronic nature that can
11 be defined, there is a mechanism.

12 MS. HOANG: That is correct, what Bram
13 just said. it is not a condition of approval. The
14 510(k) process, Bran can speak to that. I don't
15 believe it allows for conditional approval. But
16 this is a postmarket process that allows for
17 questions that would arise after the device has
18 been out in the market, if there are certain things
19 that occur that cause the agency to wonder whether
20 we should have further studies.

21 DR. TRACY: I think that the data that we
22 heard at the beginning of the day today indicates
23 that the companies are being very responsive and 90
24 percent-plus of the problems that we heard about
25 earlier were brought forth by the company. The

1 companies do not want bad products out there. They
2 are going to do this. I think we are belaboring
3 the point here because there is no company in the
4 world that I can think of that would want to close
5 their eyes if their product is having problems.
6 So, I think it is a moot point, frankly.

7 DR. YANCY: Dr. Tracy, prior to my
8 departure I just want to make one entry into our
9 record that has to do with a somewhat dissenting
10 opinion about sample size. It seems as if there
11 was a sense of agreement amongst the panel that the
12 sample sizes that were discussed were too large,
13 and it seems to me that with refinement of the
14 protocols we could achieve a sample size in the
15 400, 500 range. If, indeed, we are talking about
16 350,000 bypass procedures done per year, we are
17 talking about less than a tenth of a percent to try
18 to get into a study design, and I think that if we
19 are going to be free of these kinds of
20 deliberations in the future the appropriate study
21 design up front is necessary and I, for one, would
22 say what is required is a larger sample size. I
23 would like for it to go on the record that one
24 panel member thinks we should insist on that. I
25 think compromising now sets us up for problems

1 later.

2 DR. WHITE: Dr. Tracy?

3 DR. TRACY: Yes, Dr. White?

4 DR. WHITE: I think that we all agree with
5 Dr. Yancy as scientists and I think the
6 statisticians say the same thing. The problem is
7 reality and where your cut point is. I think we
8 need to make a decision or we need to make a
9 recommendation that it is not something we are
10 unhappy with and I personally feel very comfortable
11 with a lower bound of 90 percent patency rate. I
12 feel very comfortable that that would be a
13 reasonable device for my father and my grandfather
14 to get for a vein graft anastomosis, and if that
15 can be done with 125 patients, then I think that is
16 not an unreasonable thing. I anticipate currently
17 in many trials the benefit from this OPC criteria
18 that are not randomized and it allows more
19 investigations to be done. It allows more data to
20 be collected, and I think we ought to not put it
21 off just out of hand because it isn't randomized or
22 doesn't meet the highest standards. I acknowledge
23 that but I think there is some compromise that we
24 perhaps can make without compromising data. If we
25 can't do that without compromising data, then I

1 think Dr. Yancy is absolutely right and we should
2 insist on what we need to answer the questions.

3 DR. TRACY: I think those are both very
4 fair statements. One more comment and then we will
5 have to move on to the open public hearing. Dr.
6 Bridges?

7 DR. BRIDGES: My only comment, Chris, is
8 would you be comfortable if your anastomotic device
9 for an internal mammary had a 90 percent patency?
10 Would you be comfortable having someone use that
11 device for your internal mammary artery graft?

12 DR. WHITE: No, and I think we have all
13 agreed that we have to have two standards for
14 mammary and vein graft.

15 DR. ZUCKERMAN: But, Dr. White, the
16 calculation that Dr. Sapirstein showed was that the
17 lower confidence limit should be 0.90 for the
18 mammary example. You are now agreeing with Dr.
19 Bridges that that needs to be tightened.

20 DR. WHITE: I think the mammary needs to
21 be tightened. I think for vein graft patency that
22 would be excellent--

23 DR. BRIDGES: Right, but that is not on
24 the table. I mean, the issue was that with veins
25 we are talking 80 percent and with mammaries we are

1 talking 95 percent with a 5 percent delta. So, no
2 one is really talking about a 90 percent vein graft
3 patency. Everybody would be happy with that I
4 think. The issue is with mammaries, is 95 percent
5 the gold standard historically accepting a delta of
6 0.5; with veins is 0.8 or 0.75 or 0.85, whatever
7 you decide--I don't remember what it was he had put
8 up, it was either 0.85 or 0.8, is it acceptable?
9 So, 0.9 for a vein is really not one of the
10 questions that we were asked to look at.

11 DR. WHITE: But we get to pick. You get
12 to say what you think would make you happy. These
13 numbers that were put up were simply hypothesis. I
14 mean, they were hypothesis generating. So, we get
15 to say. What I am saying is that I am willing to
16 have a less rigorous scientific design in terms of
17 giving up randomization for vein graft patency of
18 0.9. Now, perhaps I want patency of 0.98 for a
19 mammary. Again, we get to say what the level of
20 confidence we have is if we are willing to settle
21 for a less severe scientific design.

22 DR. TRACY: Dr. Ferguson?

23 DR. FERGUSON: Further than that, we can
24 make the recommendation we want to make but it
25 sounds to me like if we are going to do an

1 extensive randomized trial on devices that have
2 already been put out there rather than "me too"
3 comparisons we are going back to a PMA format. I
4 am not sure that that is the proper direction. You
5 might want to comment on that.

6 DR. ZUCKERMAN: Everything that we
7 discussed today can be done through the 510(k)
8 clearance process. There is nothing unusual about
9 doing clinical trials for 510(k)s of this variety.

10 DR. FERGUSON: Of this magnitude? This
11 size and so on?

12 DR. ZUCKERMAN: Correct, in the coronary
13 tree. That is correct.

14 DR. TRACY: At this point I would like to
15 open the afternoon open public hearing. Is there
16 any member of the audience who wishes to address
17 the panel on today's topic? If not, we will close
18 the open public hearing.

19 I have a serious question for the FDA. It
20 says here on my script that I am supposed to
21 summarize the discussions.

22 [Laughter]

23 Do you really want me to do that?

24 DR. ZUCKERMAN: I know you can do it very
25 well. I will help you if you get into trouble but

1 I think it would be helpful for us.

2 **Summary**

3 DR. TRACY: I will give it a shot. The
4 first part we discussed, which is obviously
5 difficult thing to grapple with, was the trial
6 design. I think Dr. Blumenstein put together some
7 very nice but very quick analyses of what would be
8 entailed in doing studies with the patients serving
9 as their own controls versus randomized, controlled
10 studies.

11 The panel expressed concern over the size
12 of the trials that would be required with those
13 designs but does not want to throw out the
14 scientific rigor entirely, but also does not want
15 to throw out the historic information that we have
16 regarding 95 percent patency on the LIMA to LAD.
17 We think that there may be different study designs
18 appropriate if we are dealing with a LIMA versus a
19 saphenous vein graft trial.

20 We think that the endpoints, particularly
21 dealing with part c) of the first
22 question--surrogate endpoints are not adequate as
23 primary endpoints. The primary endpoint that we
24 think is most reliable is patency. We agree though
25 that there are other design issues that will come

1 up in some of the later questions. Have I
2 summarized the trial design part adequately?

3 Moving on to question number two with
4 regard to device placement and device design,
5 please address the following: given considerable
6 differences between the proximal and distal CABG
7 anastomoses, what, if any, differences in study
8 criteria should be required? Again, with the
9 proximal anastomoses devices there are peculiar
10 issues that come up, such as stroke, aortic
11 dissection, etc., that need to be taken into
12 account in the study design, yet the critical
13 endpoint is patency at some point based on the
14 biologic behavior of the anastomoses, and we think
15 that probably six months is an appropriate time
16 frame for that.

17 We don't think that the endpoint for a
18 proximal anastomosis study versus distal
19 anastomosis study would be different enough to
20 warrant totally different study designs. For
21 example, one shouldn't be studied at 6 months and
22 the other at 12 months. We think that there should
23 be an appropriate failure rate or success rate
24 definable at, we think, 6 months that should be
25 adequately captured with an invasive assessment at

1 that point.

2 In terms of determining conduit failure,
3 we recognize that that is difficult to understand,
4 especially since the biology of these devices isn't
5 clearly understood, and we think that a DSMB and
6 core lab would be very helpful in determining these
7 outcomes and analyzing data on a prospective basis.

8 Question number three, do you believe
9 significant differences between an arterial conduit
10 and a venous conduit warrant distinct study
11 criteria and assessment for each? If so, please
12 identify these criteria. Again, with think that
13 they certainly are biologically very different.
14 The study designs have to take into account, again,
15 the biology of the tissue but also the site of
16 anastomosis but, once again, that patency is the
17 critical outcome that we will be looking for
18 angiographically.

19 Question four, should the primary
20 effectiveness endpoint be graft patency alone, or
21 include both graft patency and myocardial
22 perfusion? We think that myocardial perfusion may
23 be misleading and we believe primary effectiveness
24 for patency is angiographic follow-up. Other
25 issues, such as aortic disruption have been

1 mentioned previously. CT and MRI, yes, those
2 endpoints that Dr. Hirshfeld brought up of looking
3 acutely and at intermediate points with CT and MR
4 would probably be appropriate acute and
5 intermediate steps to take.

6 Number five, with regard to device safety,
7 what criteria, i.e., acceptable adverse events
8 rates as compared to that for suture, should be
9 applied to the evaluation of device safety as
10 distinguished from device effectiveness, example,
11 myocardial infarction, reoperation, neurologic
12 events, we think that the same safety and
13 effectiveness endpoints that pertain to suture
14 should be applied to these devices. We do agree
15 that there is a difference between safety and
16 effectiveness, although there is some overlap in
17 terms of effectiveness but certainly safety issues,
18 such as acute aortic disruption, are safety issues
19 that should, hopefully, be seen only fairly early.

20 Endpoint evaluation with regard to
21 appropriate patient follow-up, in view of the
22 possible persisting risk of failure of some
23 mechanical anastomosis sites, distinct from
24 progression of native vessel disease, what duration
25 of follow-up is advisable for premarket evaluation?

1 Dealing specifically with premarket
2 evaluation, we think that that point of
3 angiographic intervention is the endpoint probably
4 for premarket evaluation, and we think that that
5 time point should be somewhere around the six-month
6 time.

7 Should postmarket follow-up be required to
8 assess long-term device effectiveness? If so,
9 please define the appropriate length of follow-up
10 after primary patency evaluation.

11 We believe that the answer is yes, there
12 should be some postmarket follow-up. It is in
13 everybody's best interest, in particular the
14 patients. And, that does not have to be a
15 prohibitively complex follow-up process. It could
16 be handled by a phone follow-up.

17 Number seven, can non-invasive measuring
18 instruments, echo, ultrafast spiral CT, etc., be
19 used for primary assessment of graft patency or is
20 angiographic follow-up necessary? And, at what
21 point should patency be assessed?

22 I think Dr. Hirshfeld's suggestion that
23 some form of non-invasive assessment acutely and
24 them compared with an intermediate time frame, such
25 as a three- to six-month time frame, would be

1 appropriate and that could be CT or MR. The late
2 follow-up, however, should be angiographic and that
3 should take place probably at a minimum of six
4 months of follow-up. How is that?

5 DR. ZUCKERMAN: Fantastic!

6 DR. HIRSHFELD: Question, Cindy. I didn't
7 hear the final panel recommendation on the study
8 design. I mean, we talked about several of those.
9 Is that something we should talk about or do you
10 know what you want?

11 DR. ZUCKERMAN: Right, well, what we heard
12 were the pluses and minuses of several different
13 study designs. It is an extremely difficult
14 problem. If there is consensus, we would like to
15 hear about it.

16 DR. HIRSHFELD: Well, I would just like to
17 mention that the more I think about it--I was
18 initially attracted to it but the more I think
19 about it, the more I would come down on the side
20 against the patients being their own control. We
21 just heard about a trap that it would be too easy
22 to fall into and there must be others, you know, in
23 terms of how the grafts are put on the aorta. So,
24 I don't know if you want to talk about that
25 anymore.

1 DR. TRACY: Dr. Blumenstein?

2 DR. BLUMENSTEIN: And another thing about
3 the study design is that I think that anything we
4 do today, at least we have the advantage of
5 hindsight, and any study design considered should
6 be looked at in light of whether it would have
7 detected the problems that you see in the device
8 being marketed. And, I think that is a reasonable
9 standard to apply for future designs.

10 DR. EDMUNDS: Dr. Blumenstein, is there
11 any way you could use Bayesian statistical models
12 to deal with this? Because I am really concerned
13 that this panel was convened because of concerns
14 about safety and it is more akin to concerns about
15 patency which is, of course, related to safety.
16 But to ignore the fact that, you know, 23 of them
17 popped off and the patients died, and so on, is I
18 think missing the point.

19 DR. BLUMENSTEIN: Well, I must say this
20 very carefully, when it comes to clinical trials I
21 do not worship at the altar of Bayes.

22 DR. EDMUNDS: Which altar to you worship
23 at?

24 DR. BLUMENSTEIN: The altar of
25 randomization, which aren't necessarily completely

1 disjoint but they are pretty much.

2 DR. ZUCKERMAN: Okay, but the Center for
3 Devices does also accept Bayesian randomized trials
4 or single-arm trials when appropriately designed up
5 front with our Bayesian statisticians. I am
6 wondering given Dr. Edmunds' suggestion, a lot of
7 times companies come in with European data that
8 perhaps could be used as a prior given that they
9 are going to need to potentially also supply us
10 with U.S. IDE cohort data and it would be an
11 interesting issue to further pursue given that
12 sometimes the Bayesian methodology, if correctly
13 applied, can produce smaller sample sizes. On the
14 other hand, if the prior estimates from Europe are
15 incorrect, the nice thing about Bayesian
16 methodology is that it can produce even larger
17 sample sizes.

18 DR. EDMUNDS: My concern is that we can
19 shut down a promising innovation by a lot of
20 different people and engineers, and so on, that can
21 actually make an improvement in patient care with
22 advanced coronary-artery disease, particularly if
23 they have advanced aortic disease, atherosclerotic
24 aortic disease, and it is the baby and the bath
25 water.

1 DR. BRIDGES: I am going to echo Dr.
2 Ferguson's point about the patient serving as his
3 own control. After getting more details on the
4 methodology used in the study in Hanover and
5 thinking about the logistic issues with the
6 sequence of graft placement on the ascending aorta,
7 it seems to me that no matter how you design that
8 study, it would be potentially flawed. So,
9 although I initially thought it sounded like a good
10 idea, now that I understand the details I don't
11 recommend that particular study design.

12 DR. HIRSHFELD: Since I was the bad guy
13 who initially recommended that, I would just like
14 to go on the record that I agree. I think the
15 advantage of doing the study with that architecture
16 was that you perfectly controlled for most of the
17 within patient variables. However, if doing it
18 perturbs the surgical technique from what would
19 otherwise be practiced, then that is perturbing the
20 entire study.

21 DR. TRACY: Dr. Zuckerman, were there any
22 additional comments or questions from the FDA?

23 DR. ZUCKERMAN: The agency greatly
24 appreciates the amount of time put in today by the
25 panel on what has become a very difficult issue,

1 and I am sure that the agency and industry will
2 benefit from this panel session.

3 DR. TRACY: Ms. Wells, Mr. Morton, do you
4 have any comments you would like to make at this
5 time?

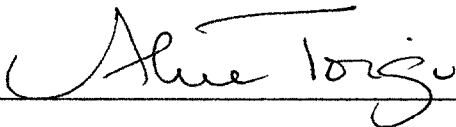

6 MR. MORTON: Just congratulations to you.
7 We are ahead of time and covered a lot of
8 territory.

9 DR. TRACY: All right, at this point we
10 will adjourn the meeting and this concludes the
11 recommendations of the panel regarding the type of
12 data and study required to effectively evaluate
13 performance of aortic anastomotic devices for
14 marketing. Thank you.

15 [Whereupon, at 4:10 p.m., the proceedings
16 were adjourned.]
